

# A quick study of $W(\rightarrow ev) + jj$ events: reconstructed $m_{jj}$ distribution

Kalanand Mishra  
*Fermilab*

# Candidate events selection

## ◆ $W \rightarrow e\nu$ reconstruction

- GsfElectron passing tight WP70 criteria
- Electron  $E_T > 20$  GeV
- W transverse mass:  $m_T > 40$  GeV
- PF MET  $> 25$  GeV
- Z veto

In sync with CDF analysis except for  $m_T$  cut (CDF requires  $m_T > 30$  GeV)

## ◆ Require two PF jets in the event

- each jet with corrected  $p_T > 30$  GeV and  $|\eta| < 2.4$
- dijet  $p_T > 40$  GeV,  $|\Delta\eta| < 2.5$
- if any 3<sup>rd</sup> jet in the event then  $p_T^{3\text{rd}} < 25$  GeV

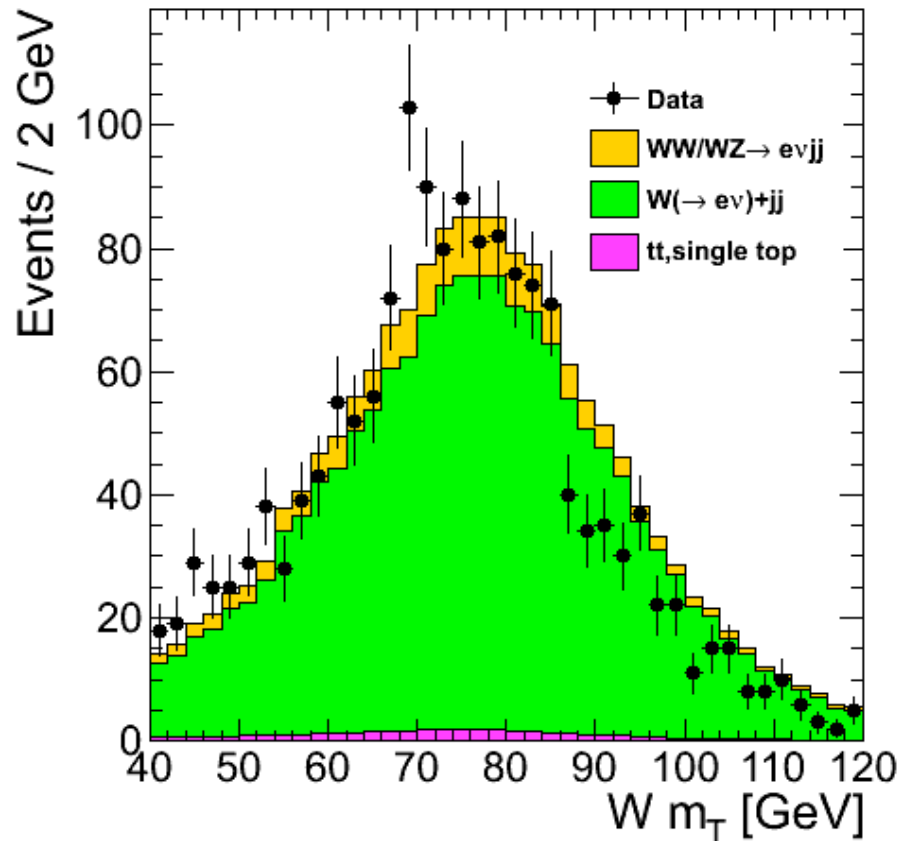

Apply standard “L2 L3” correction and “residual correction” in data

Using  $36 \text{ pb}^{-1}$  data from 2010 run

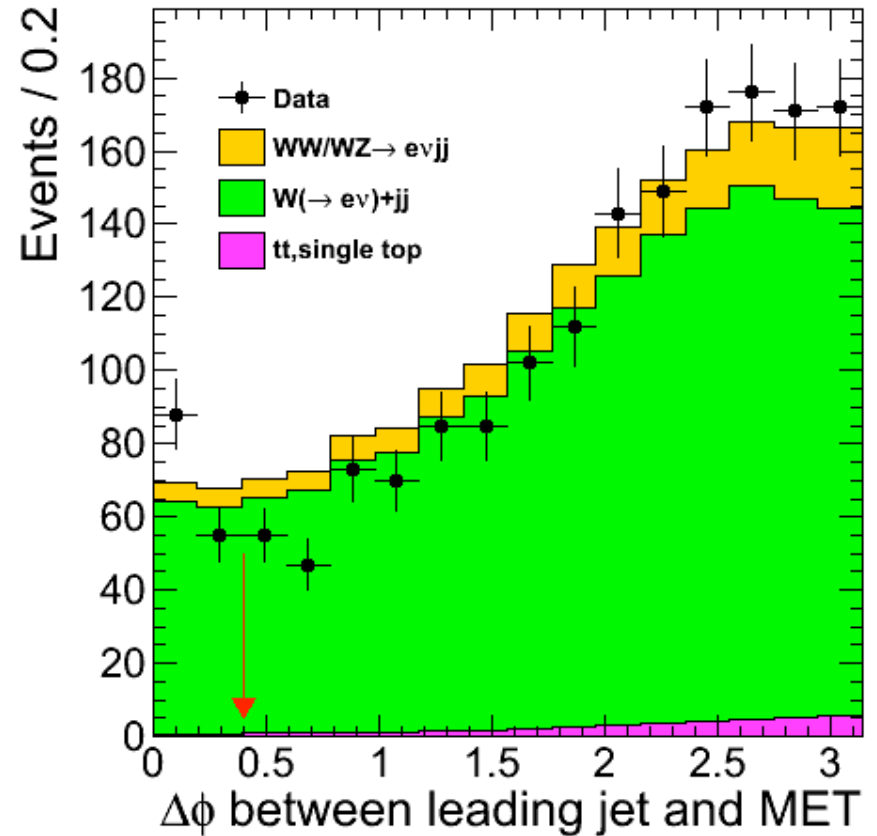

- Start with  $\sim 92000$   $W(\rightarrow e\nu) + N$  jets (where  $N \geq 2$ ) events where  $p_T^{\text{jet}} > 20$  GeV
- 1600 events pass the above-listed W+jj criteria

MC: W+jets: Madgraph, Top: Powheg, WW+WZ: Pythia  
(all with pileup conditions observed in 2010 data)

# Leptonic W and pfMET quality

W transverse mass

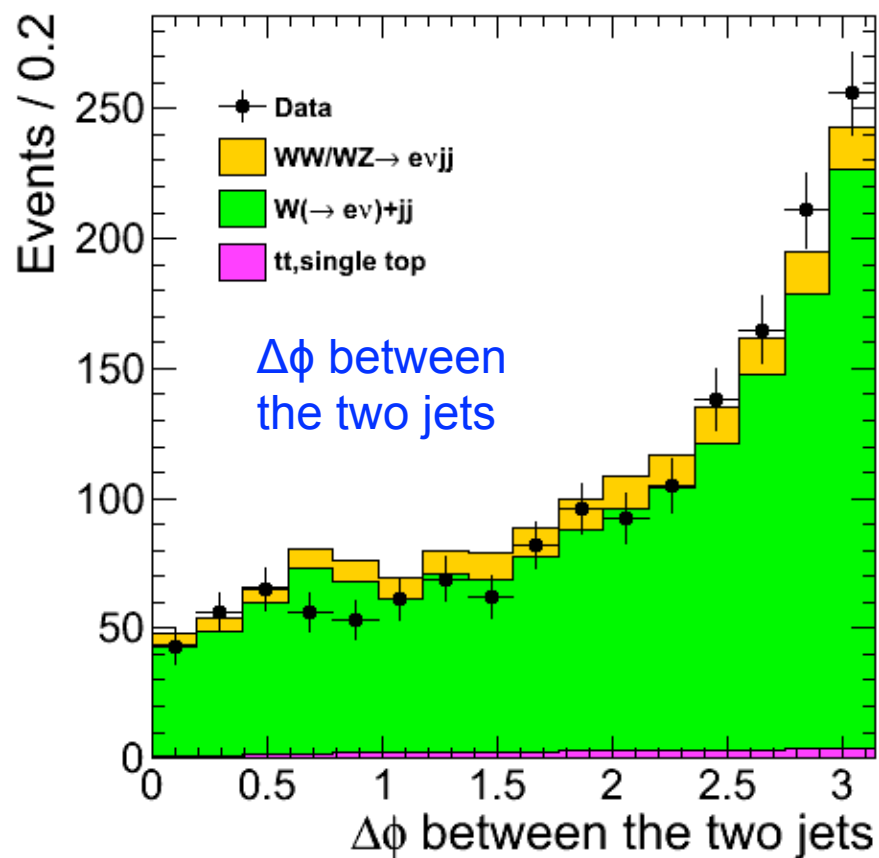

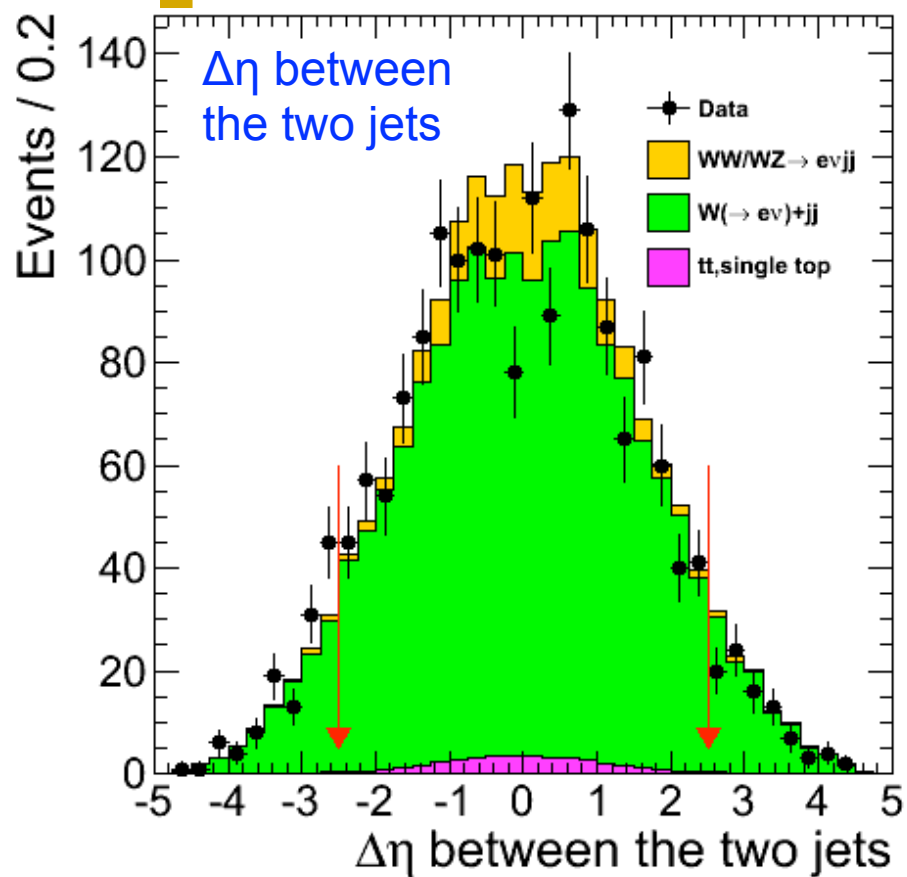

$\Delta\phi$  (jet1, pfMET)

QCD multi-jet background is small after  $m_T > 40$  GeV cut and using super tight "WP70" electron Id. I haven't run over it yet, so this background is not shown here.

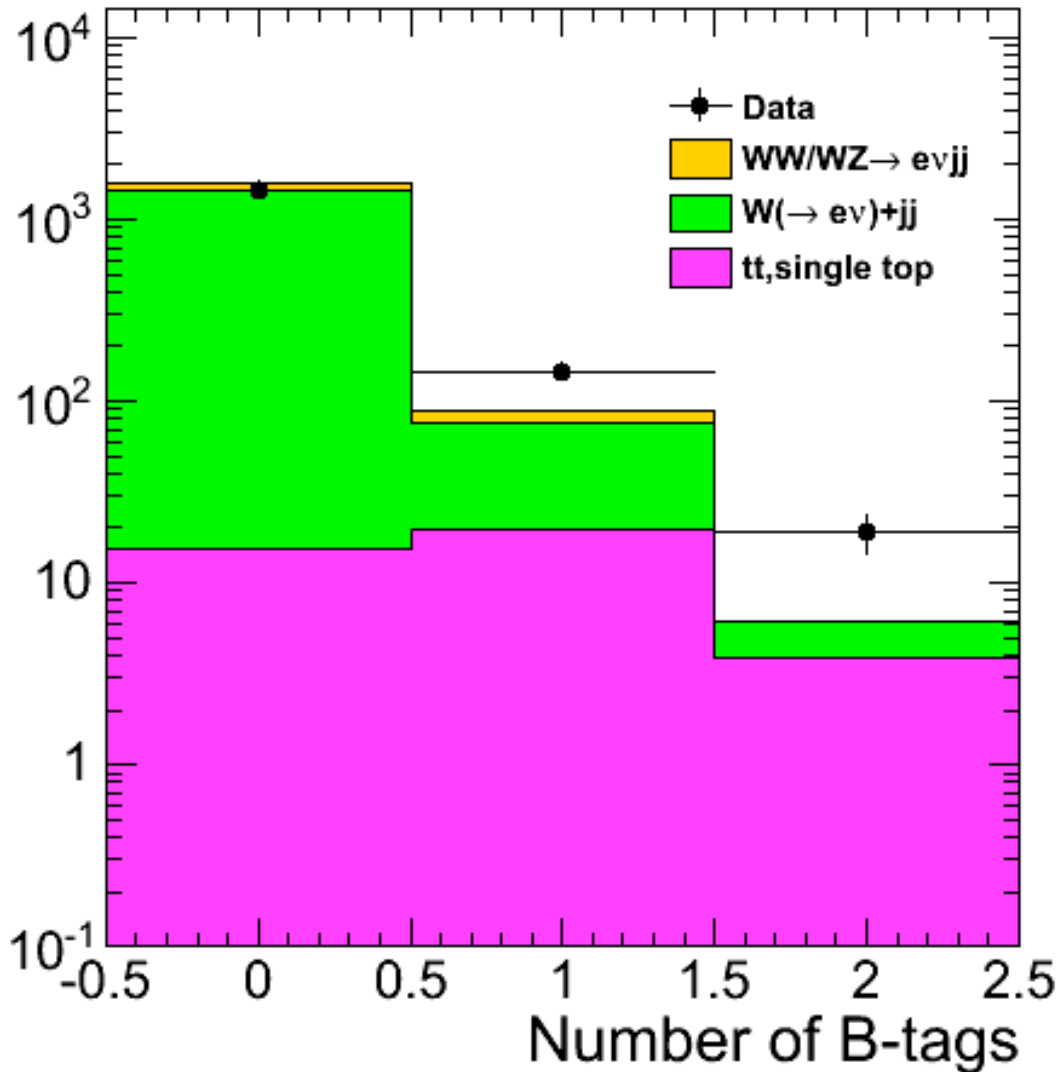

# Angular information in dijet system

# How many jets are b-tagged ?

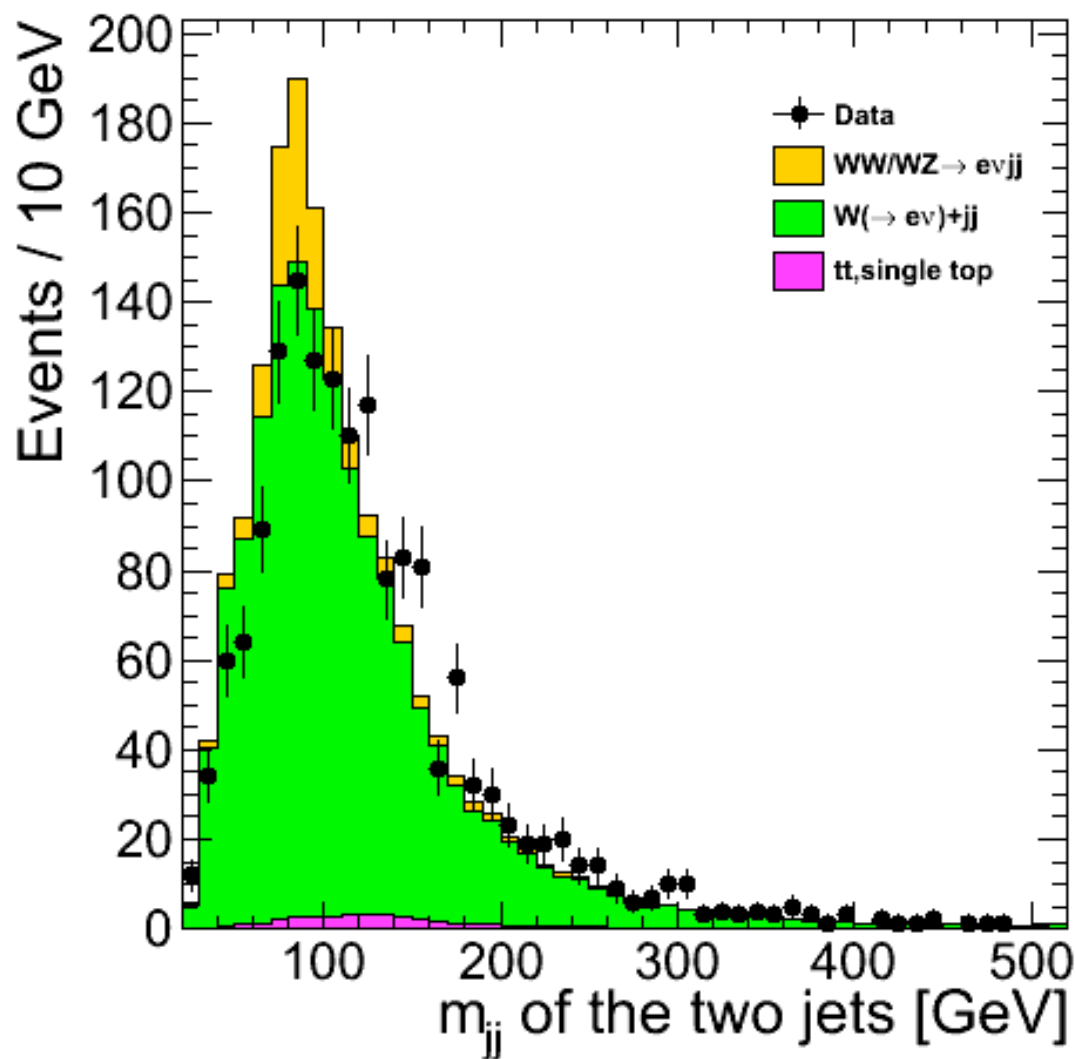

Using “simple secondary vertex (high efficiency)” medium working point.

SSV-HE medium

Potentially one can use the b-tag information to reduce/eliminate top background. But we will NOT do so in the following slides.

# $m_{jj}$ distribution for W+ $jj$ events

# observed events in data = 1595

MC predicts:

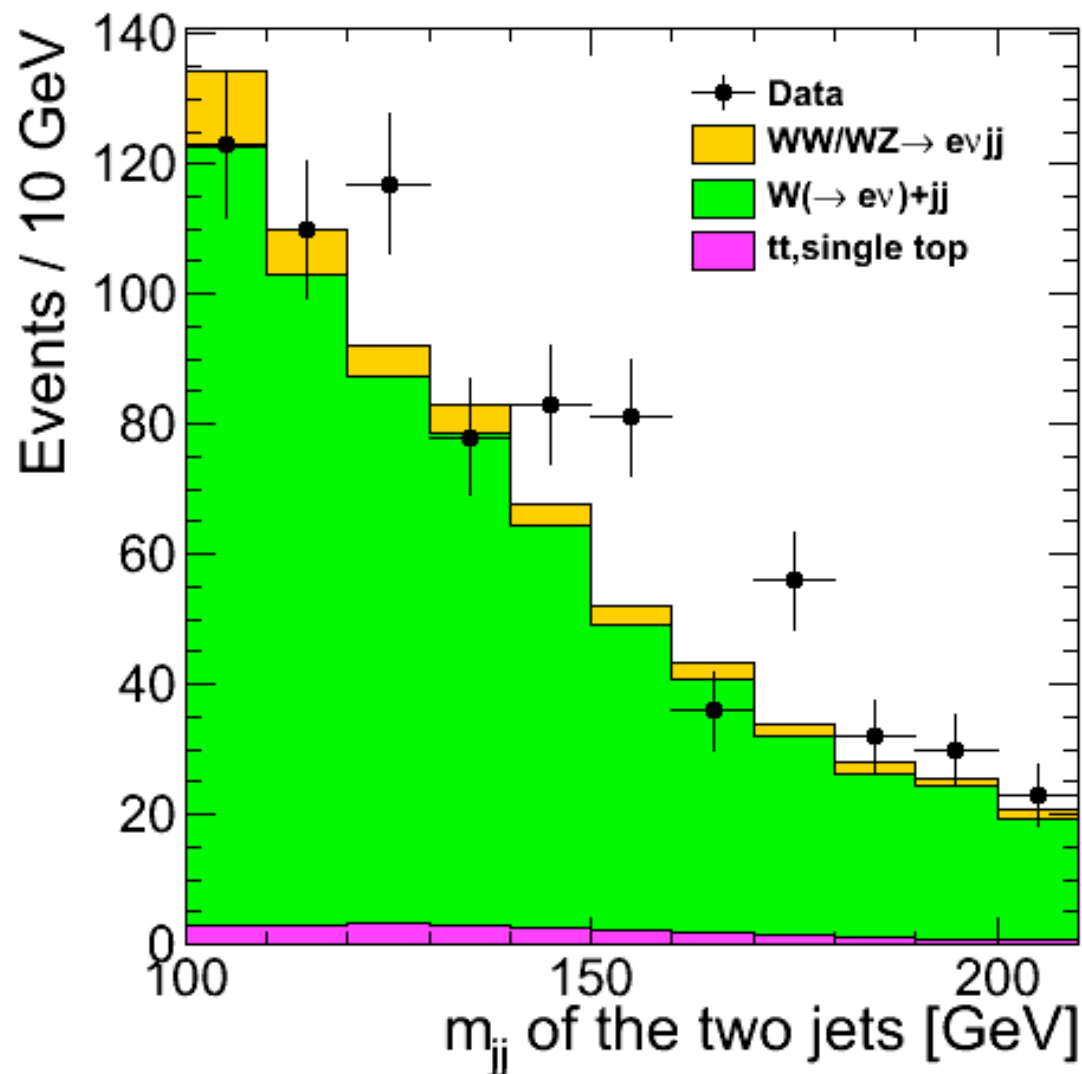

- W+ $jj$  = 1488
- WW + WZ = 165
- Ttbar + single top = 39

- Data-MC agreement depends crucially on the third jet cut
- Tighter cut on third jet makes the disagreement worse

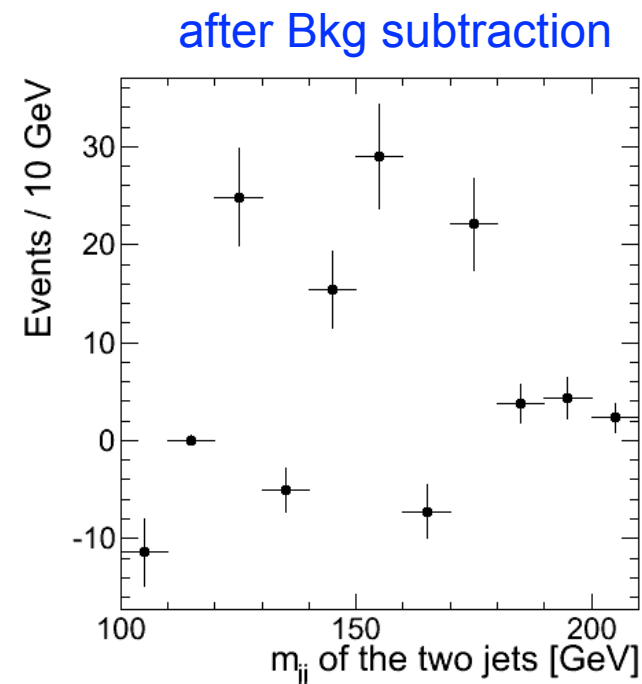

(more on this in a later slide)

Zoomed-in version of this plot on next slide  $\Rightarrow \Rightarrow \Rightarrow \Rightarrow$

# $m_{jj}$ distribution in narrow range 100-200 GeV

No clear evidence of peak in data. Error bar on data shows statistical uncertainty.

# $m_{jj}$ versus $p_T^{\text{dijet}}$

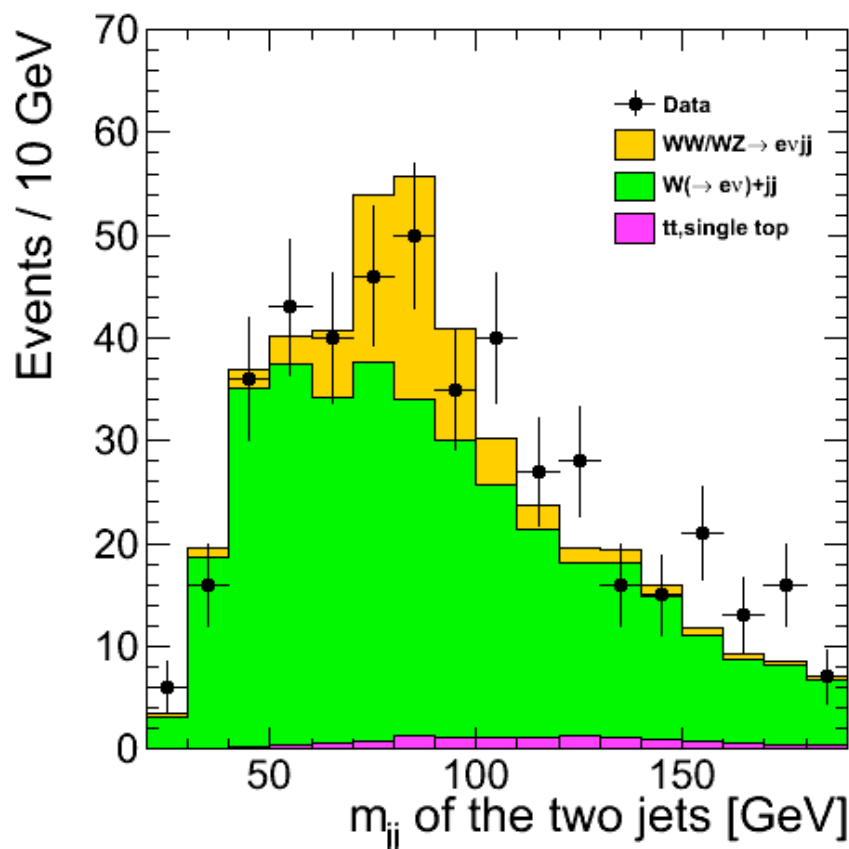

# Why I didn't see W/Z peak in $m_{jj}$ distribution?

Because the sample is dominated by  $W+jj$  events. In order to see hadronic W peak from  $WW$  events one needs to increase their relative fraction by tightening the  $\Delta\eta$  cut and requiring the hadronic and leptonic W's to be back-to-back in  $\phi$ , i.e.,  $\Delta\Phi(W^{\text{lept}}, W^{\text{had}}) \approx 180^\circ$

Require:

$$|\Delta\eta| < 1.3,$$
$$|\Delta\Phi(W^{\text{lept}}, W^{\text{had}}) - \pi| < 0.2$$

We get:

# observed events in data = 455

MC predicts:

•  $W+jj = 351$

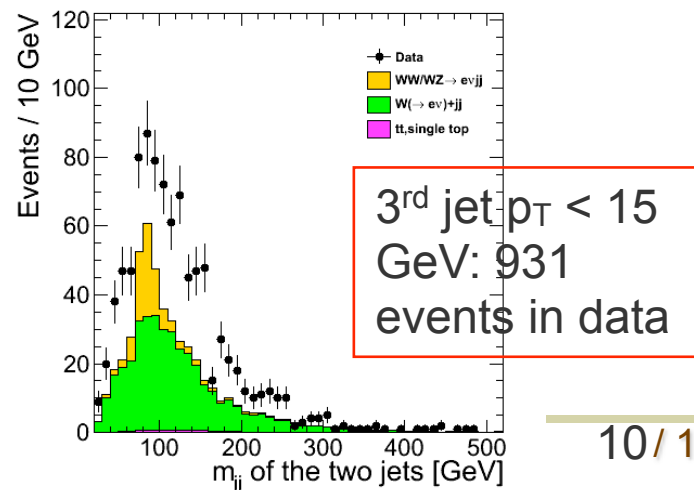

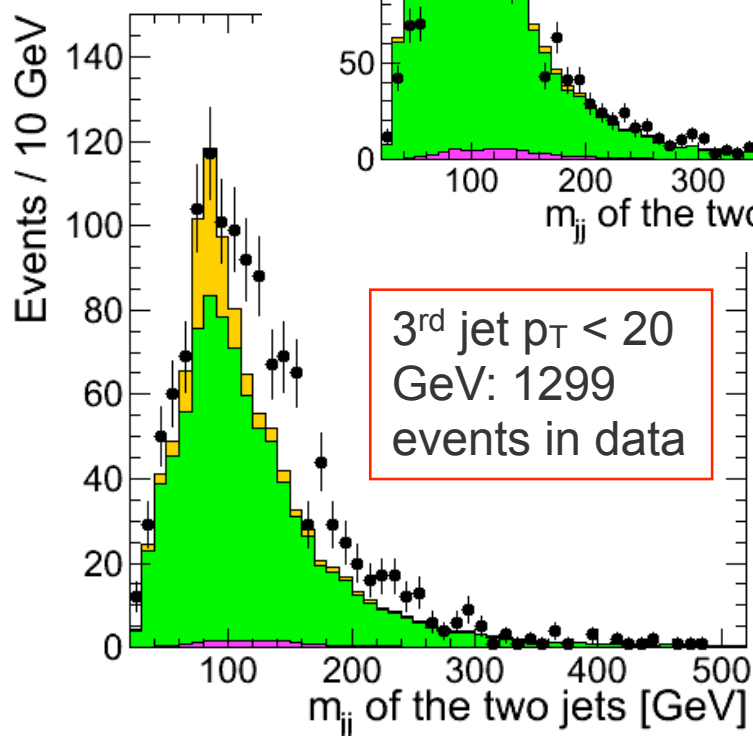

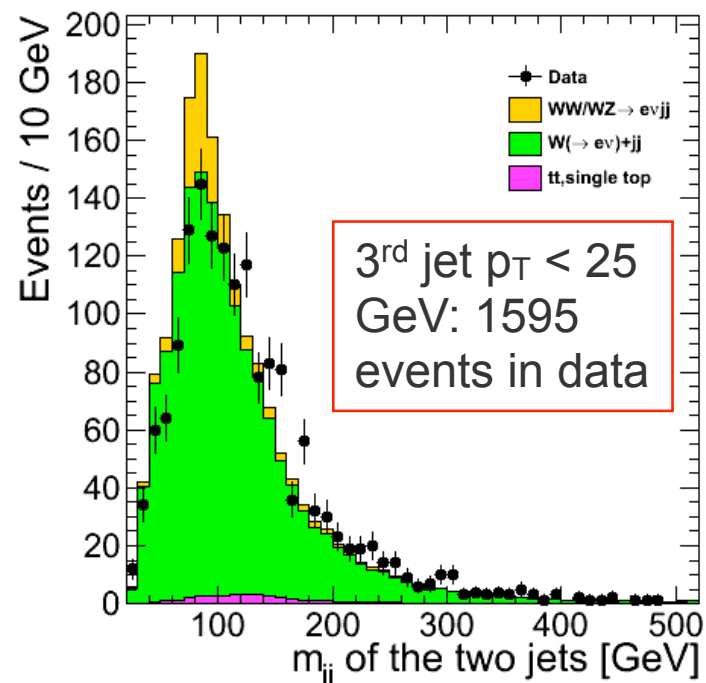

•  $WW + WZ = 74$

•  $Ttbar + \text{single top} = 12$

The shoulder from hadronic W/Z is clearly visible ( $S/B \approx 1/5-1/6$ ).

# What is the dependence on 3<sup>rd</sup> jet cut ?

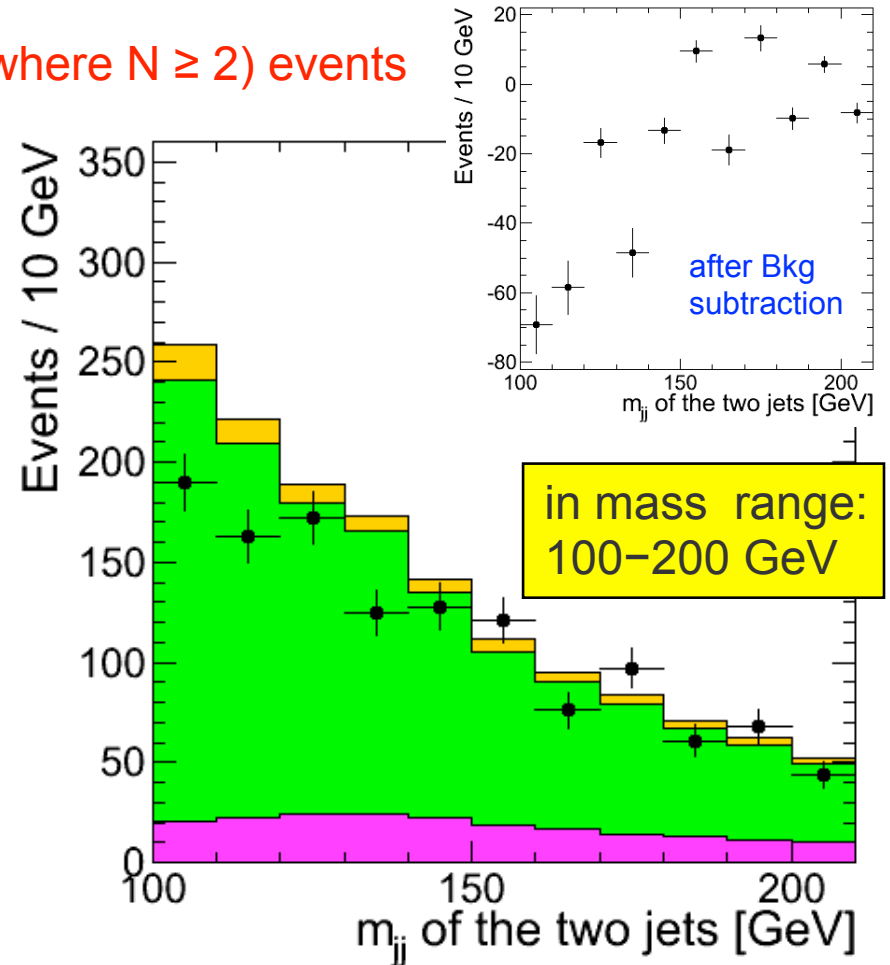

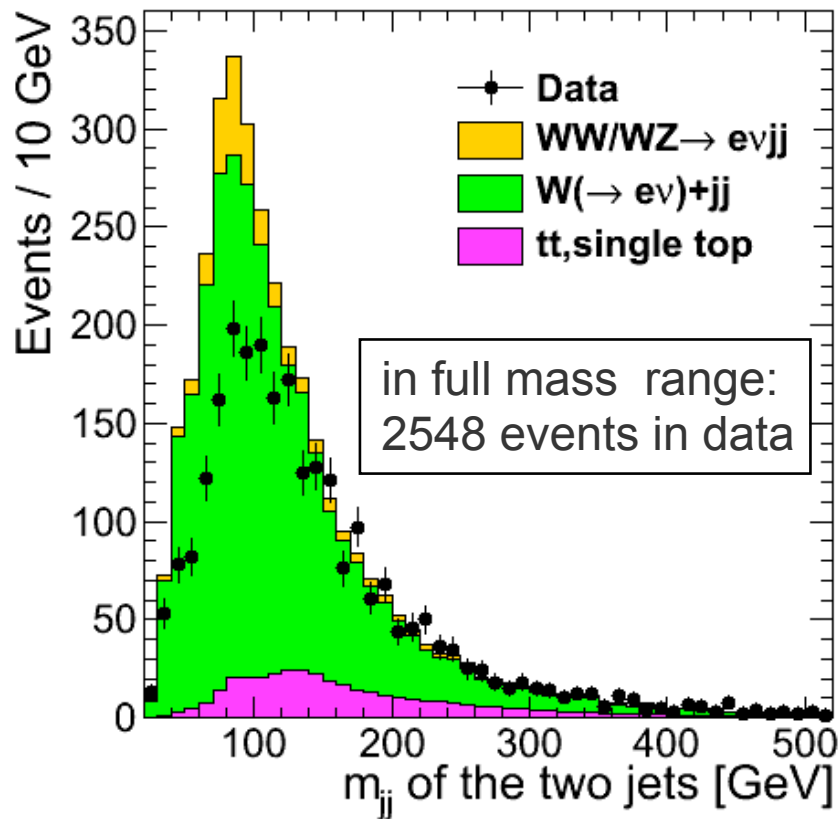

A lot ! Both normalization & shape depend on it. Data-MC agreement gets worse w/ tighter 3<sup>rd</sup> jet cut.

# What if I do not apply 3<sup>rd</sup> jet cut ?

Now looking at  $m_{jj}$  distribution in  $W+N$  jets (where  $N \geq 2$ ) events

See no excess in the mass range 100-120 GeV.
